SUMMARY

This is the case history of a 26 years old lady who was initially admitted for termination of pregnancy. She unfortunately developed a mass in the lower abdomen deviating to the left iliac fossa which was shown to be a pregnancy by ultrasonography. Therapeutic termination was done and whilst under general anaesthesia 2 separate cavities of the uterus could be probed thus raising the possibility of a bicornuate uterus. This was subsequently confirmed by a hysterosalpingogram done 6 weeks postoperatively.
